Excerpt: . . . integrated performance with minimal impact on computational resources. However, inherent assumptions in the theory limit its usefulness in producing detailed blade aerodynamic distributions for diagnostic or design information. Originally derived for analysis of cruising propellers with very slight induced velocity, these procedures are more frequently applied to rotors in hover, and low speed climb or descent. In most applications adjustments to the theory are necessary, especially to provide correct levels of induced power. These corrections may be categorized as either modifying the radial distribution of induced velocity or the overall magnitude of the induced velocity. Radial Loading Accuracy The category of corrections dealing with the modification of the radial induced velocity is the most familiar and includes the array of methods to approximate the physical boundary condition of zero loading at the streamwise edges, or tips of lifting blades. Most procedures are derived with various degrees of simplification from the original work of Prandtl and Betz as best described...
